

Effective invariants of transverse knots

Lenny Ng

Duke University

Conference on contact and symplectic topology
Université de Nantes
17 June 2011

Partly based on:

- joint work with Tobias Ekholm, John Etnyre, and Michael Sullivan
- preliminary joint work with Dylan Thurston

These slides available at <http://www.math.duke.edu/~ng/nantes.pdf>.

Outline

- 1 Transverse classification
- 2 Transverse homology
- 3 HFK grid invariant
- 4 Comparison

Transverse knots

M cooriented contact 3-manifold with contact structure $\xi = \ker \alpha$.
Standard example: $M = \mathbb{R}^3$, $\alpha_{\text{std}} = dz - y dx$.

Definition

A knot K in (M, ξ) is **transverse** if $\alpha > 0$ along K (in particular, $K \pitchfork \xi$). Two transverse knots are **transversely isotopic** if they are isotopic through transverse knots.

Transverse classification problem

Classify transverse knots of some particular topological type.

We'll restrict our attention to $(\mathbb{R}^3, \xi_{\text{std}} = \ker \alpha_{\text{std}})$.

Relation to Legendrian knots

- There is a one-to-one correspondence

$$\{\text{transverse knots}\} \longleftrightarrow \{\text{Legendrian knots}\} / \\ (+ \text{ Legendrian stabilization/destab}).$$

- In \mathbb{R}^3 , the classical invariant (self-linking number) of T and the classical invariants (Thurston–Bennequin number and rotation number) of L are related by

$$sl(T) = tb(L) - rot(L).$$

Braids and transverse knots

Theorem (Bennequin 1983)

Any braid (conjugacy class) can be closed in a natural way to produce a transverse knot in $(\mathbb{R}^3, \xi_{std})$, and every transverse knot is transversely isotopic to a closed braid.

Braids and transverse knots

Theorem (Bennequin 1983)

Any braid (conjugacy class) can be closed in a natural way to produce a transverse knot in $(\mathbb{R}^3, \xi_{std})$, and every transverse knot is transversely isotopic to a closed braid.

Transverse Markov Theorem (Orevkov–Shevchishin 01, Wrinkle 02)

Two braids represent the same transverse knot iff related by:

- conjugation in the braid groups
- **positive** stabilization $B \longleftrightarrow B\sigma_n$:

Cf. usual Markov Theorem: topological knots/links are equivalent to braids mod conjugation and positive/negative stabilization.

Transverse classification

If a transverse knot T is the closure of a braid B , the self-linking number of T is

$$sl(T) = w(B) - n(B)$$

where $w(B)$ = algebraic crossing number of B and $n(B)$ = braid index of B .

Definition

A topological knot is **transversely simple** if its transverse representatives are completely determined by self-linking number; otherwise **transversely nonsimple**.

Transverse classification

If a transverse knot T is the closure of a braid B , the self-linking number of T is

$$sl(T) = w(B) - n(B)$$

where $w(B)$ = algebraic crossing number of B and $n(B)$ = braid index of B .

Definition

A topological knot is **transversely simple** if its transverse representatives are completely determined by self-linking number; otherwise **transversely nonsimple**.

Examples of transversely simple knots:

- unknot (Eliashberg 1993)
- torus knots (Etnyre 1999) and the figure 8 knot (Etnyre–Honda 2000)
- some twist knots (Etnyre–N.–Vértési 2010)

Transverse nonsimplicity

Examples of transversely nonsimple knots:

- $(2, 3)$ -cable of $(2, 3)$ torus knot (Etnyre–Honda 2003) and other torus knot cables (Etnyre–LaFountain–Tosun 2011)
- some closed 3-braids (Birman–Menasco 2003, 2008)
- some twist knots (Etnyre–N.–Vértési 2010): number of crossings in shaded region is odd and ≥ 5

Transversely nonsimple knots: Birman–Menasco examples

Birman–Menasco 2008: family of knots with braid index 3 that are transversely nonsimple. More precisely, they show that the transverse knots given by the closures of the 3-braids

$$\sigma_1^a \sigma_2^b \sigma_1^c \sigma_2^{-1}, \quad \sigma_1^a \sigma_2^{-1} \sigma_1^c \sigma_2^b,$$

which are related by a “negative flype”, are transversely nonisotopic for particular choices of (a, b, c) .

$$\sigma_1^5 \sigma_2^3 \sigma_1^3 \sigma_2^{-1}$$

$$\sigma_1^5 \sigma_2^{-1} \sigma_1^3 \sigma_2^3$$

Effective transverse invariants

Definition

A transverse invariant is **effective** if it can distinguish different transverse knots with the same self-linking number and topological type (i.e., prove that some topological knot is transversely nonsimple).

Not known to be effective:

- Plamenevskaya 2004: distinguished element in Khovanov homology
- Wu 2005: distinguished elements in Khovanov–Rozansky \mathfrak{sl}_n homology
- N.–Rasmussen 2007: distinguished element in Khovanov–Rozansky HOMFLY-PT homology (known not to be effective)

Effective transverse invariants, continued

Known to be effective:

- Ozsváth–Szabó–Thurston 2006: **HFK grid invariant**: distinguished element in knot Floer homology via grid diagrams
- Lisca–Ozsváth–Stipsicz–Szabó 2008: LOSS invariant: distinguished element in knot Floer homology via open book decompositions
- Ekholm–Etnyre–N.–Sullivan 2010: **transverse homology**: filtered version of knot contact homology

The conormal construction

Idea: use the cotangent bundle to turn smooth topology into symplectic/contact topology.

- M smooth manifold \rightsquigarrow unit cotangent bundle ST^*M , which is naturally a **contact** manifold
- $K \subset M$ embedded submanifold \rightsquigarrow conormal bundle

$$N^*K = \{(q, p) : q \in K, \langle p, v \rangle = 0 \forall v \in T_q K\} \subset ST^*M,$$

which is a **Legendrian** submanifold of ST^*M .

Smooth isotopy of $K \subset M$ results in *Legendrian* isotopy of $N^*K \subset ST^*M$.

Knot contact homology

$$(K \subset M \implies N^*K \text{ Legendrian} \subset ST^*M \text{ contact})$$

Any *Legendrian-isotopy invariant* of N^*K is a *smooth-isotopy invariant* of K : for instance, **Legendrian contact homology** (Eliashberg–Hofer), where defined. For $M = \mathbb{R}^n$, $ST^*M = J^1(S^{n-1})$ and LCH is well-defined (Ekholm–Etnyre–Sullivan 05).

Definition

$K \subset \mathbb{R}^n$. The **knot contact homology** of K is the Legendrian contact homology of $N^*K \subset ST^*\mathbb{R}^n$,

$$HC_*(K) := LCH_*(N^*K).$$

In particular, for a knot $K \subset \mathbb{R}^3$, $HC_*(K)$ is a smooth knot invariant.

Form for knot contact homology

$$(K \subset M \implies N^*K \text{ Legendrian} \subset ST^*M \text{ contact})$$

For a knot $K \subset \mathbb{R}^3$, the LCH complex for N^*K is a differential graded algebra

$$(CC_*(K), \partial)$$

generated by Reeb chords for N^*K , over the group ring

$$R := \mathbb{Z}[H_1(N^*K)] \cong \mathbb{Z}[\lambda^{\pm 1}, \mu^{\pm 1}].$$

The differential counts holomorphic disks in $ST^*\mathbb{R}^3$ with boundary on N^*K .

Theorem (N. 2003, 2004, Ekholm–Etnyre–N.–Sullivan in preparation)

There is a purely algebraic/combinatorial expression for the DGA $(CC_(K), \partial)$.*

Holomorphic disks counted in knot contact homology

The symplectization $\mathbb{R} \times ST^*\mathbb{R}^3$, and the Lagrangian cylinder $\mathbb{R} \times N^*K$ in the symplectization:

Holomorphic disks counted in knot contact homology

The symplectization $\mathbb{R} \times ST^*\mathbb{R}^3$, and the Lagrangian cylinder $\mathbb{R} \times N^*K$ in the symplectization:

This holomorphic disk contributes

$$\partial(a_i) = a_{j_1} a_{j_2} a_{j_3} + \cdots$$

where $a_i, a_{j_1}, a_{j_2}, a_{j_3}$ are Reeb chords of N^*K .

Properties of knot contact homology

(Recall: knot contact homology $HC_*(K) =$ Legendrian contact homology of conormal $N^*K \subset ST^*\mathbb{R}^3$.)

Theorem (N. 2004)

- $HC_*(K)$ can be combinatorially shown to be a knot invariant, supported in degrees $* \geq 0$.
- (Linearized) $HC_1(K)$ encodes the Alexander polynomial $\Delta_K(t)$.
- $HC_0(K)$ detects the unknot.

Lifting a contact structure

Given a contact manifold (M, ξ) , the contact structure ξ itself has a conormal lift to ST^*M :

$$N^*\xi = N_+^*\xi \cup N_-^*\xi = \{(q, p) \in ST^*M : \langle p, v \rangle = 0 \forall v \in \xi_q\}.$$

If K is **transverse** to ξ , then the conormal lifts of K and ξ are disjoint: $N^*K \cap N_\pm^*\xi = \emptyset$.

Filtering the LCH differential

If K is transverse in (\mathbb{R}^3, ξ) , we can **filter** the LCH differential for N^*K by counting intersections with the holomorphic 4-manifolds $\mathbb{R} \times N_{\pm}^*\xi$ in the symplectization $\mathbb{R} \times ST^*\mathbb{R}^3$.

Filtering the LCH differential

If K is transverse in (\mathbb{R}^3, ξ) , we can **filter** the LCH differential for N^*K by counting intersections with the holomorphic 4-manifolds $\mathbb{R} \times N_{\pm}^*\xi$ in the symplectization $\mathbb{R} \times ST^*\mathbb{R}^3$.

This lifts the LCH complex from a DGA (\mathcal{A}, ∂) over $R = \mathbb{Z}[\lambda^{\pm 1}, \mu^{\pm 1}]$ to a DGA $(\mathcal{A}, \partial^-)$ over $\mathbf{R}[U, V]$: e.g.

$$\partial^-(a_i) = U^2 V^1 a_{j_1} a_{j_2} a_{j_3} + \cdots$$

Transverse homology

Definition

The **(minus) transverse complex** of a transverse knot $K \subset (\mathbb{R}^3, \xi_{\text{std}})$ is the LCH algebra $(CT_*^-(K) = \mathcal{A}, \partial^-)$ over the base ring $R[U, V] = \mathbb{Z}[\lambda^{\pm 1}, \mu^{\pm 1}, U, V]$, with the differential ∂^- filtered by intersections with $N_{\pm}^* \xi$.

This can be viewed as a bi-filtered version of knot contact homology.

Theorem (Ekholm–Etnyre–N.–Sullivan 2010)

- *There is a combinatorial formula for $(CT_*^-(K), \partial^-)$ in terms of a braid representative of K .*
- *The **transverse homology** of K , $HT_*^-(K) = H_*(CT^-(K), \partial^-)$, is a transverse invariant.*

Flavors of transverse homology

From $(CT^-(K), \partial^-)$ chain complex over $R[U, V]$ (with $R = \mathbb{Z}[\lambda^{\pm 1}, \mu^{\pm 1}]$), obtain:

- $(\widehat{CT}_*(K), \widehat{\partial})$ chain complex over R , by setting $(U, V) = (0, 1)$ or $(1, 0)$
- $(CT_*^\infty(K), \partial^\infty)$ chain complex over $R[U^{\pm 1}, V^{\pm 1}]$, by tensoring with $R[U^{\pm 1}, V^{\pm 1}]$
- $(CC_*(K), \partial)$ chain complex over R , by setting $(U, V) = (1, 1)$

$\widehat{HT}_*(K)$ is a transverse invariant, while $HT_*^\infty(K)$ and $HC_*(K)$ are topological invariants (the latter is knot contact homology).

Theorem (N. 2010)

$\widehat{HT}_0(K)$ is an effective transverse invariant.

Example: $m(7_6)$ knot

$$\sigma_1 \sigma_2^{-1} \sigma_1 \sigma_2^{-1} (\sigma_3^3 \sigma_2 \sigma_3^{-1})$$

$$\sigma_1 \sigma_2^{-1} \sigma_1 \sigma_2^{-1} (\sigma_3^{-1} \sigma_2 \sigma_3^3)$$

These two transverse $m(7_6)$ knots can be distinguished by \widehat{HT}_0 :
count number of augmentations (ring homomorphisms)

$$\widehat{HT}_0 \rightarrow \mathbb{Z}/3.$$

This is an effective technique for distinguishing other transverse knots, as long as braid index $\lesssim 4$.

HFK grid invariant

Ozsváth–Szabó–Thurston 2006:

transverse knot T of topological type K

distinguished element $\theta^-(T) \in \text{HFK}^-(m(K))$.

In combinatorial model for CFK via grid diagrams
(Manolescu–Ozsváth–Sarkar), $\theta^-(T)$ is the generator given by the upper-right corners of the X's for a Legendrian approximation of T .

HFK grid invariant, continued

Result (after mapping $HFK^- \rightarrow \widehat{HFK}$) for T transverse of type K :

$$\widehat{\theta}(T) \in \widehat{HFK}_{sl(T)+1}(m(K), \frac{sl(T)+1}{2}).$$

Theorem (Ozsváth–Szabó–Thurston 2006)

The HFK grid invariant $\widehat{\theta}$ is a transverse invariant.

Crude way to apply $\widehat{\theta}$: if T_1, T_2 are transverse knots with $\widehat{\theta}(T_1) = 0$ and $\widehat{\theta}(T_2) \neq 0$, then they're distinct.

Theorem (N.–Ozsváth–Thurston 2007)

The HFK grid invariant $\widehat{\theta}$ is an effective transverse invariant.

E.g., can be used to recover Etnyre–Honda's result that the $(2, 3)$ -cable of the $(2, 3)$ torus knot is transversely nonsimple.

Limitations of crude approach

$$\widehat{\theta}(T) \in \widehat{HFK}_{sl(T)+1}(m(K), \frac{sl(T)+1}{2}) :$$

- If this group is 0, then $\widehat{\theta}(T) = 0$ carries no information.
- If $\widehat{\theta}(T_1), \widehat{\theta}(T_2) \neq 0$, how to tell them apart?

Slightly more precise statement of invariance:

Theorem (Ozsváth–Szabó–Thurston 2006)

If T_1, T_2 are isotopic transverse knots and G_1, G_2 are grid diagrams of corresponding Legendrian approximations, then the transverse isotopy gives a sequence of grid moves from G_1 to G_2 inducing a combinatorially-defined isomorphism

$$\phi : \widehat{HFK}(G_1) \rightarrow \widehat{HFK}(G_2)$$

and $\phi(\widehat{\theta}(G_1)) = \widehat{\theta}(G_2)$.

Enter naturality

Theorem (Thurston et al., in progress)

(roughly speaking) Let G_1, G_2 be grid diagrams for the same topological knot, and let γ be a sequence of grid moves from G_1 to G_2 . Then the isomorphism

$$\gamma_* : \mathrm{HFK}^-(G_1) \rightarrow \mathrm{HFK}^-(G_2)$$

depends only on the homotopy class of the path $\gamma \subset \{\text{smooth knots}\}$.

Definition

Let K be an oriented topological knot. The **mapping class group** of K is

$$\mathrm{MCG}(K) = \pi_1(\{\text{smooth knots isotopic to } K\}).$$

Can use naturality in conjunction with $\hat{\theta}$.

Naturality and the HFK grid invariant

Corollary

Let T_1, T_2 be transverse of type K with $MCG(K) = 1$, and let G_1, G_2 be grid diagrams for T_1, T_2 . If T_1, T_2 are transversely isotopic, then for any sequence γ of grid diagrams from G_1 to G_2 ,

$$\gamma_*(\widehat{\theta}(G_1)) = \widehat{\theta}(G_2).$$

Theorem (N.–Thurston 2011, preliminary)

The Birman–Menasco pair

$$\sigma_1^5 \sigma_2^3 \sigma_1^3 \sigma_2^{-1} \quad \text{and} \quad \sigma_1^5 \sigma_2^{-1} \sigma_1^3 \sigma_2^3$$

can be distinguished by $\widehat{\theta}$.

Birman–Menasco transverse knots

$$\sigma_1^5 \sigma_2^3 \sigma_1^3 \sigma_2^{-1}$$

$$\sigma_1^5 \sigma_2^{-1} \sigma_1^3 \sigma_2^3$$

These are of topological type $11a_{240}$, and $MCG(11a_{240}) = 1$. The $\widehat{\theta}$ invariants constitute distinct nonzero elements of

$$\widehat{HFK}_8(11a_{240}, 4) \cong (\mathbb{Z}/2)^2.$$

This argument can be extended to other Birman–Menasco pairs (possibly $\sigma_1^a \sigma_2^b \sigma_1^c \sigma_2^{-1}, \sigma_1^a \sigma_2^{-1} \sigma_1^c \sigma_2^b$ for $a, b, c \geq 3$ with $a \neq c$), but not all of them.

Transverse mapping class group

Definition

Let K be a transverse knot. The **transverse mapping class group** of K is

$$TMCG(K) = \pi_1(\{\text{transverse knots transversely isotopic to } K\}).$$

For a transverse knot K , there is an obvious map

$$TMCG(K) \rightarrow MCG(K).$$

Naturality and $\hat{\theta}$ can be used to show that this map is not an isomorphism for some transverse knots K .

Transverse mapping class group, continued

Theorem (N.–Thurston 2011, preliminary)

Consider any twist knot where the number of crossings in the shaded region is odd and ≥ 3 .

There is a transverse knot K of this topological type such that the map

$$TMCG(K) \rightarrow MCG(K) (\cong \mathbb{Z}/2)$$

is not surjective.

Cf. Kálmán 2004: there are Legendrian knots K for which the map $LMCG(K) \rightarrow MCG(K)$ is not *injective*.
